Dr, Robert L. Stephenson
State Archeologist and
Director
Institute of Archeology and
Anthropolôgy
University of South Carolina

Dear Dr. Stephenson,

Enclosed is a draft manuscript encompassing the data and preliminary results of my ceramic analysis distributional study, that I have worked on over the past year. I will be working this material into a form suitable for publication over the next year, and will submit it to you upon completion of the report.

This report enables present investigators to make use of the data that I have accumulated. Since it may be two years before a final report is released I felt that a draft manuscript with the data would be of value to investigators in the interim. I have sent a copy of the report to the Charleston Museum and this copy should be placed in the Institute files and made available as needed. I will be working up the data herein, but its use in studies other than distributional is something I am more than willing to permit and in fact hope for.

If any investigators wish to make use of this data for distributional studies they should receive my written permission. In this way duplication of effort can be avoided.

I have enjoyed working on this study and hope that it can be of value in future archeological investigations in the South Carolina area. I will, again, send you the final report when it is completed.

Sincerely,
A handwritten signature in cursive script that reads "David G. Anderson".

and Ethnological Collections
The Charleston Museum
Charleston, S.C.

27 June 1975

Dear Al,

I have enclosed a copy of a recent ceramic analysis distributional study that I have been working up over the last year. In it are the data for in the Charleston Museum whose collections I examined last fall. The report and the data sheets should be of value to you in your handling of the materials. I will forward a final copy of this report, with plates, when I have completed it. That should be some time in the next two years.

This report and information are the preliminary results of my work here at the I.A.A. on Coastal Plain ceramics over the last year. I am making the data available prior to the final release of the report because I feel that it can be of immediate value to investigators in this area. Its use in analytical distributional studies should follow only after written permission from me has been obtained, so that duplication of effort does not occur.

I have enjoyed working with you and the other staff members at the Museum these past two years. I still have three museum potsherds I'll deliver the next time I'm home, and you can be sure I'll drop in whenever I'm in the Charleston area.

Sincerely,
David G. Anderson

Introduction

The intent of this paper is to shed some light on what has long been a relatively unknown area archeologically within the Southeast - the coastal plain of South Carolina. In particular it focuses on the distribution of prehistoric ceramics in the light of the available data from this area. In addition to seeking to determine and demonstrate distributional patterning within prehistoric coastal ceramics, this report also has the additional goal of elucidating associations between these ceramic complexes and various environmental factors present within the coastal plain.

Unlike her neighboring states of North Carolina and Georgia, South Carolina has, until recently, been largely ignored archeologically. Thus, while the work of Coe (1964), Haag (1956), and South (1959, 1960) has done much to reveal the outlines of the prehistoric occupation of coastal North Carolina, and in Georgia the WPA related activity of Caldwell, McCann, Waring, and others throughout the state and particularly along the Savannah (as recounted by Waring 1968a), led to an early general awareness of the archeological resources of that state, South Carolina has remained for the most part an unknown. At various meetings of the Southeastern Archeological Conference, for example, when the distributions of ceramic assemblages in the region were discussed the South Carolina area was either ignored (Kneberg 1962; Fairbanks 1962) or else mentioned, usually by Waring (in Sears 1966: 2; Waring 1968b), in passing. Thus many people had a vague or intuitive idea of what was supposed to be present, but there were few examples of hard data to verify these opinions.

This condition has persisted almost to the present day. Thus, recent investigations along the Savannah River at Groton Plantation by Stoltman (1974) and Peterson (1971a), and Milanich's general statement on the southeastern

Deptford culture (1971) have all pointed out the lack of data for most of the South Carolina area. In terms of distributional studies Waddell's work in the early 1960's (1963; 1965) delimiting the range of Thom's Creek and Awendaw pottery, and Ferguson's recent work on the distribution of 'South Appalachian Mississippian mound sites (1971) form the only available data encompassing the entire South Carolina coastal plain.

A primary orientation of this study was towards determining what kinds of prehistoric ceramics were present in the coastal plain of South Carolina, and where within the coastal plain these ceramics were to be found. As noted, there has been virtually no work along these lines in this state. The ultimate goal of this study is towards elucidating causal factors behind the observed distributions; at the present time extensive correlations of the ceramic data with a wide range of environmental variables is underway.

This report and the included data are a preliminary statement. A comprehensive report utilizing the appended data will be submitted to the Institute of Archeology and Anthropology in 1976. Because the data that this report is based on is of value to current archeological investigations in the South Carolina area it is being made available considerably prior to the final report release. Additional associations and investigations using this data are presently underway, and the results of this research will appear with the final report. Investigators seeking the use of this data for the preparation of distributional studies similar to those presented here must receive written permission from the author.

Paste Attributes

The analysis of the ceramic fabric or paste has long been recognized as an extremely useful and productive tool in both classificatory and processual studies. The role of constituent paste elements in the development of taxonomic frameworks is hardly unknown in the Southeastern United States, where some of the most intensively studied ceramic materials have been delimited largely on the basis of criteria such as "fiber tempering" or "sherd tempering". Five specific paste characteristics and an open category for materials not covered in the first five were utilized. These are listed horizontally across the top of the data sheet (fig.) and include Fiber, FS/Clay, FS/Grit, Sherd, Shell, and Other. Paste categories were delimited by the presence or absence of tempering material, and were established to permit rapid macroscopic sorting.

Fiber

Fiber tempering (fig.) is widely recognized as an indicator of a very early ceramic horizon in the Southeast (Waring 1968c, Stoltzman 1974). Griffin (1943) first described the paste of Stalling's fiber-tempered ware, using ceramics from the Chesterfield site, and his description can be little improved upon:

"Varying proportions of a fiber which has almost uniformly disappeared in firing, presenting a vesicular appearance. In some examples there is a very small amount of fiber while in others the sherd is honey-combed (1943: 159-160).

Other inclusions, such as sand, may be present in the paste, but the presence of fiber tempering, once established, places the sherd in this category rather than in another. The only exceptions would be trace or accidental inclusions, particularly on the exterior surface where the plastic vessel may have rested on plant material prior to firing.

FS/Clay

Paste characterized by particles ranging in size from medium sand to clay, using the modified Atterberg grade scale (Butzer 1971: 164) in which medium sand equals .06 - .2mm and clay equals under .002 mm. These particle sizes are so small that the paste is in effect almost "temperless" to macroscopic visual examination, although a sizable proportion of sand may be present and even felt when rubbing the surface of the sherd. The use of "FS" implies a very Fine Sand (i.e. fine grained) may be present in the paste, although the actual size range includes medium grade sand. The occasional occurrence of a larger sized inclusion in an otherwise temperless or visually nearly temperless paste was considered accidental and not sufficient for the placement of a sherd in another paste category. South (1960: 47) noted that all of the Thom's Creek punctated sherds that he recovered along part of the North and South Carolina Coast had "no tempering aplastic"; the use of this paste category was to check this observation and to see if other wares were characterized by a temperless or nearly temperless paste.

FS/Grit

Paste characterized by the presence of macroscopically visible inclusions of sand (fig.); using the modified Atterberg grade scale as a reference this would refer to pastes with coarse sand (.2 - 2.0 mm) and occasionally fine pebbles (2.0 - 6.0 mm) present. The presence of more than two inclusions of this size range on any sherd break was considered other than chance and grounds for the inclusion of the sherd in this category. No effort was made to separate natural and intentionally crushed inclusions; all of the materials observed appeared to have naturally formed inclusions.

Sherd

Paste characterized by the presence of lumps of clay or ground-up sherd (fig.). These lumps occasionally produce a rough lumpy appearance on one or both surfaces of a sherd, and may be considerably different in color and texture than the surrounding body of the sherd. Other inclusions may be present, such as sand, but the presence of clay or sherd lumps places the sherd in this category. Sherds with both fiber and sherd tempering were not encountered, nor are expected. Clay and sherd tempering has been recognized by Caldwell & Waring (1939) and South (1960) as being of considerable significance in the South Carolina Coastal Plain; at the present it is used to indicate a Wilmington (South 1973) component.

Shell

Paste characterized by the inclusion of shell fragments, or other inclusions that contain a high content of calcium carbonate (fig.). Sherds tempered in such a fashion will appear highly pock-marked with small holes due to the shell leaching out (South 1960: 41), or will contain inclusions that are generally whitish colored. Material recovered from shell middens with favorable preservation conditions may contain unleached shell fragments; tests for the presence of possible shell tempering were conducted using both 10% and 50% HCl solutions on scrapings from inclusions (after Shepard 1971: 381). These tests suggest the presence of calcium carbonate, and hence shell or marl, through the visible effervescence that occurs upon application of the acid. The effervescence is carbon dioxide gas given off in the reaction:

The tests demonstrated the probable presence, through visible effervescence, of shell tempering at a number of sites.

Other

This category includes all specimens not specifically covered under the first five paste categories. This would include steatite, bone, or some other temper not specifically covered. In the present study only one sherd was observed that was placed in this paste category. This was a sherd of steatite tempered ware (fig.) that was recovered from the Mulberry Mound (38KE12).

Surface Finish Attributes

Twenty-five specific surface finish categories, a category for non-diagnostic or unrecognizably finished sherds, and an Other category for unusual specimens were recorded, and are listed vertically on the left hand side of the data sheet (fig.). The term surface finish refers to the condition of the sherd's exterior surface and includes treatment that might be regarded as either decorative or functional. Attachments such as nodes or tetrapodes, and decorative techniques such as stamping or notching that were applied to the rim area were ignored in this study. The terminology used generally follows that established by Ford and Griffin (1939) and Shepard (1971).

Punctate, linear sep.

Linear separate punctations; a linear arrangement of indentations made with a tool or finger while the paste was plastic. Each punctation is separated from the next nearest punctation (fig.), an effect caused by completely removing the tool from the surface of the vessel prior to the next application. The tool may be reed, bone, shell, or anything capable of producing a punctation. This category includes all separately punctated sherds with the exception of sherds punctated exclusively near the rim, as is sometimes seen on Pee Dee and Irene ceramics (Caldwell & Waring 1939, Reid 1967).

Punctate, drag & jab

A linear arrangement of continuous punctations made with a tool or finger while the paste is plastic. The tool is not removed from the vessel surface between punctations, rather it is "dragged" prior to indentation. This results in a continuous linear decoration (fig.) that can approach an incised appearance if the punctations are close enough together (fig.).

Punctate, random

Random punctations applied to the surface of a vessel while the paste is plastic. No linear or other pattern can be discerned in the spacing of the punctations, which may occur on part or over the surface of the vessel (fig.).

Punctate, geometric

Punctations applied to the surface of the vessel, while the paste is plastic, that form a discernable geometric pattern (fig.). Triangles, circles, or zig-zag lines may be defined, and occasionally complex patterns may occur (fig.); these complex patterns may not be strictly geometric but are included in this category.

Finger-pinched

Raised impressions on the surface of the vessel made by pinching the plastic paste with two fingers (fig.). Finger-pinched ceramics are considered to be characteristic of "Awendaw" ware (Waddell 1965, South 1973). The impressions are usually linear but may be isolated, or randomly applied.

Dentate stamped

A single or double row of small square or rectangular indentations in a linear arrangement (fig.) made with either a roulette stamp or a narrow paddle while the paste was plastic. Holmes (1903: 75-76) illustrates this form of decoration, which has been associated with Refuge ceramics in the South Carolina Coastal Plain (Peterson 1971, South 1973). The impressions are usually arranged linearly with some occasional over-stamping.

Incised, fine

Lines up to 1mm wide drawn or cut in the paste of the vessel (fig.). These lines are usually drawn while the paste is plastic, but may be drawn (engraved) even after firing. Incised lines may assume any orientation, and may be combined to form intricate patterns. Closely spaced drag-and-jab decorations may be confused with incising and in all probability served a similar decorative role.

Incised, wide

Lines over 1mm wide drawn on the surface of the vessel (fig.), usually while the paste was plastic, although occasionally drawn (engraved) after firing.

SS, parallel thin

Parallel simple stamped impressions. A parallel arrangement of impressions with the space between the raised lands up to 2mm wide, apparently made with either a carved paddle or a thong-wrapped paddle (Fig.). Ferguson (personal communication) has suggested that the design effect may be obtained in many cases by using a split piece of wood as a paddle. Parallel simple stamping

results from the application of a parallel carved or wrapped paddle, in one orientation, without cross stamping, to the plastic surface of a vessel. The impressions may be either smooth or rough in appearance, but should not have twists or other attributes suggesting cord or fabric impressions.

SS, parallel thick

Parallel simple stamped impressions with distances greater than 2mm between the raised lands, made while the vessel paste was plastic (fig.).

SS, cross thin

Cross simple stamped impressions. The distances between the raised lands of the impressions are less than 2mm wide (fig.). The cross stamping results from either over stamping with a parallel grooved paddle or a parallel thong-wrapped paddle, or through application of a cross carved or wrapped paddle, or both. The stamp was applied while the paste was plastic.

SS, cross thick

Cross simple stamped impressions on the vessel surface with the distances between the raised lands greater than 2mm wide (fig.). The stamp was applied while the vessel paste was plastic.

Cord, parallel thin

Parallel cord impressions with a cord width up to 1mm wide (fig.) created by the application of a cord-wrapped paddle to the plastic paste of the vessel. The twist of the cords is usually discernable, and the occurrence of this twist is the primary attribute to observe. If no discernable twist impressions are noted the sherd is not to be placed in the category of cord-marked.

Cord, parallel thick

Parallel cord impressions with a cord width over 1mm wide (fig.). The stamp is created by the application of a cord-wrapped paddle to the plastic paste of the vessel.

Cord, cross thin

Cross stamped cord impressions. The width of the cord is up to 1mm wide, and the impressions result from the over stamping of a parallel cord-wrapped paddle, or from stamping with a cross wrapped paddle (fig.). The impressions were applied while the vessel paste was plastic.

Cord, cross thick

Cross stamped cord impressions. The cord width is over 1mm wide and the impressions were applied while the paste of the vessel was plastic (fig.).

Linear checkstamped

"The design consists of a repeated parallel arrangement of two longitudinal lands which contain a series of finer transverse lands.... The longitudinal lands are invariably heavier and usually higher than the transverse lands" (Caldwell & Waring 1939) (fig.).

The lands are formed by the carving of grooves in a wooden paddle; the stamp is applied when the paste of the vessel is plastic. The thicker size of the longitudinal lands gives the stamp a linear appearance.

Check stamped

The design consists of a lattice of evenly-sized raised lands that intersect to form square or rectangular checks (fig.). The even size of the lands produces a regular grid, which distinguishes this design from linear check stamped. The stamp is created through the application of a carved wooden paddle to the surface of the vessel while the paste is plastic.

Fabric, loose wv

Fabric impressions characterized by a loose, poorly defined weave (fig.). The impressions are applied while the paste was plastic. Both warp and weft elements are soft and evenly defined.

Fabric, rigid wv

Fabric impressions characterized by a rigid warp element, about which a flexible cord was laced (fig.). The impressions were applied while the vessel paste was plastic. The rigid warp element creates a longitudinal land giving sherds a linear stamped appearance.

Fabric, net

Net impressions characterized by a regular knotted mesh. The finish was applied while the paste was plastic and the twists in the cords making up the mesh are apparent. The ware can be confused with cross cord-marked pottery, but the knots and the regular mesh size distinguish it.

Plain

Plain sherds have an unaltered surface finish, with variation present only in the nature and extent of surface smoothing. No subdivisions of this category, based upon criteria such as extent of smoothing, were recorded.

Complicated thin

Complicated stamp characterized by thin, closely spaced lands. The space between the lands in this category is up to 1mm wide (fig.). The stamp is applied with a carved wooden paddle while the vessel paste is plastic. Design motifs are curvilinear or rectilinear and include concentric circles, filfot crosses, bar-diamonds, figure eights, and a number of other patterns.

Complicated med

Complicated stamped ceramics characterized by lands spaced 1 to 2mm apart (fig.). The stamp is applied with a carved wooden paddle while the paste of the vessel is plastic.

Complicated thick

Complicated stamped ceramics characterized by thick, widely spaced lands over 2mm apart (fig.). The stamp is applied while the paste of the vessel is plastic.

Other (specify)

This category includes all ceramics possessing a recognizable surface finish that is not specifically listed. Included in this category would be sherds with combinations of two or more of the attributes listed. In addition to occasional sherds with combinations of attributes, in this study a small number of corrugated sherds were noted.

Nondiagnostic

Sherds with a surface finish that is unrecognizable, either through weathering, heavy over stamping, or some other factor, belong in this category. Unless the surface finish of a sherd can be determined with certainty it should be included in this category.

Interpretation

A total of 342 collections from 315 sites were investigated. In fig. 1 dots represent the sites whose ceramic assemblages were investigated; not included are sites reported by independent researchers whose data was examined for degree of congruity with the data generated by this investigation. In particular the published work of Phelps's (1968), Stoltman (1974), Peterson (1971), and Waring (in Williams 1968), as it related to the Savannah River area, Ferguson's work on South Appalachian Mississippian (1971), and South's work in coastal North Carolina (1960) were utilized. In Figures 2 through the significant distributions observed as a result of this study are presented.

The artifact samples examined in the preparation of this study were gathered in a variety of ways over a period of 50 years by collectors with widely varying degrees of motivation and training in archeological sampling and recovery techniques. The probability of a high level of inherent bias in the sample must be therefore considered. Comparison of the data with the published material mentioned above has had encouraging results, however, suggesting that its validity is fairly good.

Analysis of the data as reported here was accomplished by a breakdown of the coastal plain into several sectors in an attempt to relate observed distributions with environmental variables such as river drainages or soil and forest covers. For purposes of efficient communication the data have, where possible, been incorporated into South's taxonomic framework for coastal South Carolina pottery, which was presented at the 1973 meeting of the SEAC (South 1973). This taxonomic framework is hierarchical in nature and proceeds from established type descriptions at one end of the classificatory spectrum through ascending orders of integration utilizing ware,

ware-group, and ware-group evolution levels of inclusiveness. Thus for purposes of communication and investigation it is more convenient to talk of "Stalling's ware-group" material when referring to local fiber-tempered ceramics, rather than attempt to enumerate all the types or variants.

The occurrence of Stalling's ware-group material as a minority ware along the South Carolina coast was noted by Waring (1968c: 255), and South (1960: 55,64) has reported a few isolate sherds from coastal North Carolina. Outside of the Savannah River area its inland distribution has remained unknown, although Griffin (1945: 467) reported one sherd of this material in his discussion of ceramics from the Thom's Creek site.

In the present sample (Fig.) Stalling's ware-group material was noted along the coast to just beyond Charleston Harbor, and inland along all the major river drainages. Moving northeastward from the Savannah River, the Edisto is the last drainage with a high incidence of this material; along the Santee and Pee Dee rivers fiber-tempered pottery occurs with very low frequency. If we can accept the non-statistically random procedures with which these materials were collected, then this decrease in occurrence on the total number of sites in any drainage or coastal area as one moves north has been further corroborated statistically. The distribution on sites in the geographic areas investigated was first checked by the Chi-square test and found to have a significant nonrandom distribution. Using Spearman's formula for rank correlation this decrease in incidence as one moved northeast from the Savannah was found to have a .90 correlation (Table 1).

Based on the present sample, I would hypothesize the following distribution of this ware group in coastal South Carolina - the area delimited in Fig. represents the area where Stalling's material seems to occur both in large quantities on individual sites and on large numbers of sites.

TABLE 1

STALLING'S FIBER - TEMPERED POTTERY : STATISTICAL ANALYSIS

OF DISTRIBUTION⁻¹

<u>DATA:</u> Geographic Sector*	# Sites with Stalling's/Total # sites investigated	%
PeeDee River drainage(inland)	7/38	18.4
Santee River drainage(inland)	9/46	19.6
Edisto/Salkahatchie drainage (inland)	7/17	41.2
Savannah River drainage (inland)	15/39	38.5
Santee River-N.C. Border (coastal)	0/10	0.0
St. Helena Sound- Santee River (coastal)	6/26	23.1
Savannah River- St. Helena Sound (coastal)	16/27	59.3

One Sample Chi-square Test

$$\chi^2 = 21 \quad df = 6 \quad p < .01$$

Spearman's Formula for Rank Correlation

$$r_s = .89 \quad p < .01$$

* "Coastal" geographic sectors refer to those areas from the seacoast to 10 miles inland, "Inland" sectors are those from ten miles inland to the fall line.

-1 Using 203 sites- total as of October 1974.

Thom's Creek is generally regarded as representative of the earliest sand-tempered ceramics along the Savannah River, overlying and probably later than Stalling's material in that area (Phelps 1968: 29; Stoltman 1974: 236). The type Thom's Creek Punctate as defined by (Waddell 1963) was chosen as a convenient and relatively unambiguous diagnostic for establishing the distribution of this ware (Fig.). This choice was made because of the difficulties apparent in selecting and separating Deptford, Refuge, and Thom's Creek material, particularly simple stamped and plain types. This is a problem that both Waring (1968d: 200) and Peterson (1971: 143-148) have noted in their work with these ceramics.

Thom's Creek punctated pottery occurred with the highest frequency and incidence on sites along the Santee and Edisto Rivers, and in the corresponding coastal sector, in the Charleston County area. As one moved either north or south of this area, the incidence and frequency of this type decreased markedly. Along the Savannah River, for example, the type was found on a very low percentage of the sites investigated, with a frequency of less than 1% of the total assemblage. The work of Stoltman on Groton Plantation (1974: 209) and South in coastal North Carolina (1960: 65) has yielded similar distributional and frequency data to that recovered in this study, and allows me to hypothesize that the Santee and Edisto River region form the primary center of occurrence for this ware.

The relationship of Thom's Creek ware to the fiber-tempered Stalling's ware group material has been a matter of professional interest for a number of years, particularly as more and more radiocarbon dates accumulate suggesting a long degree of overlap in the temporal ranges of each taxa. Although Thom's Creek and Stalling's ceramics would appear from this study to have different centers of popularity, in inland South Carolina away from the Savannah River a high percentage of the sites where fiber-tempered material occur also have

Thom's Creek material. In the region of the Edisto River, both inland and along the coast, a large number of sites were observed in this study with both wares present, and it is probable that work in this area would help resolve this question of relationship. Along the coast Waddell (1963; 1965; and), Hemmings (1970), Sutherland (1973; 1974), Michie (1973), and Trinkley (1974) have recently been working on this problem.

Refuge ceramics are generally regarded along the Savannah River as a temporally intermediate ware between Stalling's and Deptford ceramics (Waring 1968d: 208). The type Refuge Dentate stamped (Waring 1968d: 200; Peterson 1971: 126-127) was chosen as a diagnostic indicator. This assumes that dentate stamping is an accurate indicator of Refuge, an assumption I feel should be tested further, although the work of Waring and Peterson does support this assumption. The present study suggested a low incidence of this ware along the Savannah (Fig.), which may reflect a position of dentate stamping as a minority type within the series, a position in fact suggested by the data of Waring (1968d: 198-200) and Peterson (1971: 127, 163). I feel that this probably also reflects a distributional factor, as dentate stamping was observed at a number of sites in central South Carolina.

Given the data at hand I would suggest a hypothetical center of popularity for this ware along the Santee River. Of particular interest, in the sample inspected, was the clear association of the ware with Thom's Creek and Deptford ceramics. Of the 17 sites in this study in central South Carolina with Refuge ware present, 16 had Thom's Creek material, and 13 of the 17 sites were associated with Deptford ceramics. Sears and Waring have both suggested an evolutionary sequence operating within these assemblages (Sears 1966: 2, 20); while I feel that it is premature to draw any conclusions, I would nevertheless state that the data is suggestive.

Deptford linear check stamped pottery (Caldwell & Waring 1939) was chosen as a diagnostic indicator for distributional studies of this ware. The type had a marked incidence on sites along the Edisto and Santee Rivers (Fig.), while in areas to the north and south in the coastal plain a sharp decrease both in incidence and frequency was observed. Along the coast this material is reported almost exclusively from incidental finds, and large sites with the ware present were noted only at the mouths of two extensive drainages, the Savannah and the Santee. This observation has also been noted by Trinkley & Carter in their Charleston County coastal survey (1975). Inland, Deptford sites were recorded along all of the drainages, suggesting an adaptation to the rich resources of this area.

The term Cape Fear ware-group has been proposed by South (1960: 38-41; 1973) to encompass all ceramics characterized by a sandy or non-tempered paste with cord, fabric, or net impressions found in the coastal plain of South Carolina. This study indicates that Cape Fear ceramics are found throughout the coastal plain (Fig.). Inspection of the data led to the discovery of a marked patterning in the distribution of the fabric marked ceramics. As one proceeds south from the North Carolina area, both on the coast and inland the frequency and incidence of fabric marked pottery steadily drops, until along the Savannah it is virtually nonexistent.

Using data from surveys by South (1959: 231) and Haag (1956) from northern North Carolina, coupled with South's data from southern coastal North Carolina (1960: 65), and the data of this survey, the pattern was even more pronounced. Over ten discrete geographic areas investigated, using Spearman's formula for rank correlation, a negative .95 correlation between incidence of fabric marked pottery and location south of the Virginia-North Carolina border was observed (Table 2).

In 1939 Caldwell and Waring defined the type Wilmington Heavy cord-marked to refer to a sherd or sand-tempered ware that they observed along the Georgia coast and at the mouth of the Savannah at Wilmington Island. Generally regarded as a hallmark of an intrusion from the north (Waring 1968b: 221; Caldwell 1958: 33-34), the ware is particularly characterized by the use of ground-up sherds or particles of fired clay as a tempering agent in many of the specimens observed.

In 1960, South, working in southern coastal North Carolina and northern South Carolina, observed and described a sherd-tempered ware characterized by cord and fabric surface treatment that he classified as Hanover (1960: 36-38). At that time South and Waring communicated and decided to utilize separate terminology since the ceramics of the intervening distance were unknown (South: personal communication).

As can be seen (Fig.), the data indicate that sherd-tempered ware occurs more or less continuously along the coast from Georgia to North Carolina. Interestingly enough, the same pattern of distribution for fabric marked pottery occurs with this ware as does with Cape Fear sand-tempered ware - as one moves south the incidence and frequency of fabric drops markedly. Inspection of sherd-tempered assemblages from sites along the South Carolina coast has revealed the relationship of Hanover to Wilmington ware. Material from the Savannah River area called Wilmington is generally thicker, sandier, and somewhat more poorly made than material to the north. The variation is slight, however, and can be detected only in assemblages from the northern and southern areas and not from the individual sherds; within these assemblages individual sherd-tempered sherds may be readily substituted in assemblages over the area.

Along and to the north of the Santee River, sherd-tempered ware is found inland and is characterized by a far higher incidence of fabric marked pottery

CAPE FEAR FABRIC MARKED POTTERY : STATISTICAL ANALYSIS

OF DISTRIBUTION ⁻¹

DATA: Geographic Sector*	# Sites Cape Fear fabric/Total # of sites investigated	%

* Geographic sectors are arranged from northernmost to southernmost in this table.

-1 Using 203 sites-total as of October 1974.

than the coastal area to the south. Of particular interest is the almost complete lack of sherd-tempered material inland in the coastal plain south of the Santee River. This lack of sherd-tempered cord and fabric ware compared with the presence of Cape Fear sand-tempered cord and fabric ware for the same area strongly suggests a temporal or cultural basis for the observed dichotomy. I would suggest for convenience that sherd-tempered material recovered in the South Carolina area can be best referred to under the heading of South's "Wilmington ware-group" (1973). Such a heading avoids the confusion involved in dealing with sherd and sand-tempered wares with the same surface finish (cord or fabric marking) but with somewhat different geographic ranges when paste is also examined. Thus, strict utilization of the original Wilmington type description, for example, with its emphasis on both sherd and sand tempering, can lead to possibly erroneous conclusions. The use of "Cape Fear" and "Wilmington" ware-group terminology provides for a finer taxonomic breakdown and classification of the observed data.

The term Chicora has been suggested by South (1973) as a convenient taxonomic category for the complicated stamped South Appalachian Mississippian ceramics that occur in the South Carolina area. Chicora ceramics were found along the coast and inland along the rivers in the coastal plain to the fall line, but they occur primarily along major river systems that drain the Piedmont and only rarely along rivers originating in the coastal plain (Fig.). These major river systems, as well as being excellent lines of communication, are also potentially highly favorable to agricultural food production, if one accepts Murphy and Hudson's hypothesis (1968) that intensive agriculture in the Southeast at this period may be related to regular flooding of the rivers, allowing for periodic soil enrichment. Those rivers which have large numbers of sites with South Appalachian Mississippian ceramics present also have extensive piedmont drainage networks capable of picking up a considerable sediment load that would be partially dropped in the reduced gradient of the

coastal plain.

Ferguson, in a paper presented at the SAA meetings in Norman, Oklahoma in 1971, discussed the distribution of South Appalachian Mississippian sites in the Atlantic coastal plain, and at that time offered an explanation based on the nature and richness of the local soils for the rather novel appearance of sites of this period below the fall line in this part of the Southeast (nd: 5-7). His thesis developed from the observation that forest maps indicate that the relative homogeneity of the forest pattern in the coastal plain of north Florida and in Georgia is markedly disturbed in South Carolina (U.S.G.S. 1969), which could be explained by soil richness and variability. The coastal plain of South Carolina is thus seen as characterized by relatively rich soils and, it may also be noted, by extensive bottomland hardwood swamps (U.S. Army Corps of Engineers 1972: 9). This combination of factors produces a rich biotope quite probably perfectly capable of supporting, on a year round basis, the extensive inland settlements that appear to be reflected in the distributions of ceramics in this area from the earliest periods (Ferguson: personal communication).

From the ceramic distributions presented it would appear that coastal South Carolina, particularly in the region of the Santee River, formed a relatively intensive occupational center during the late prehistoric period. The occurrence of extensive bottomland hardwood swamps and a diverse forest and soil cover are suggested as factors behind this richness in cultural material (as elaborated by Ferguson: 1971; nd). Furthermore, the interaction between areas to the north and southeast of the South Carolina coastal plain may be seen reflected in the data.

Conclusions

This paper has sought to present some of the more interesting discoveries resulting from this study. The data presented represents only a small percentage of that obtained. A large number of other, equally significant distributions have also been found. Among these include new discoveries such as a lack of decorated fiber-tempered pottery for much of the interior of South Carolina, and a virtual absence of tetrapods, or base supports for pots, over the same area.

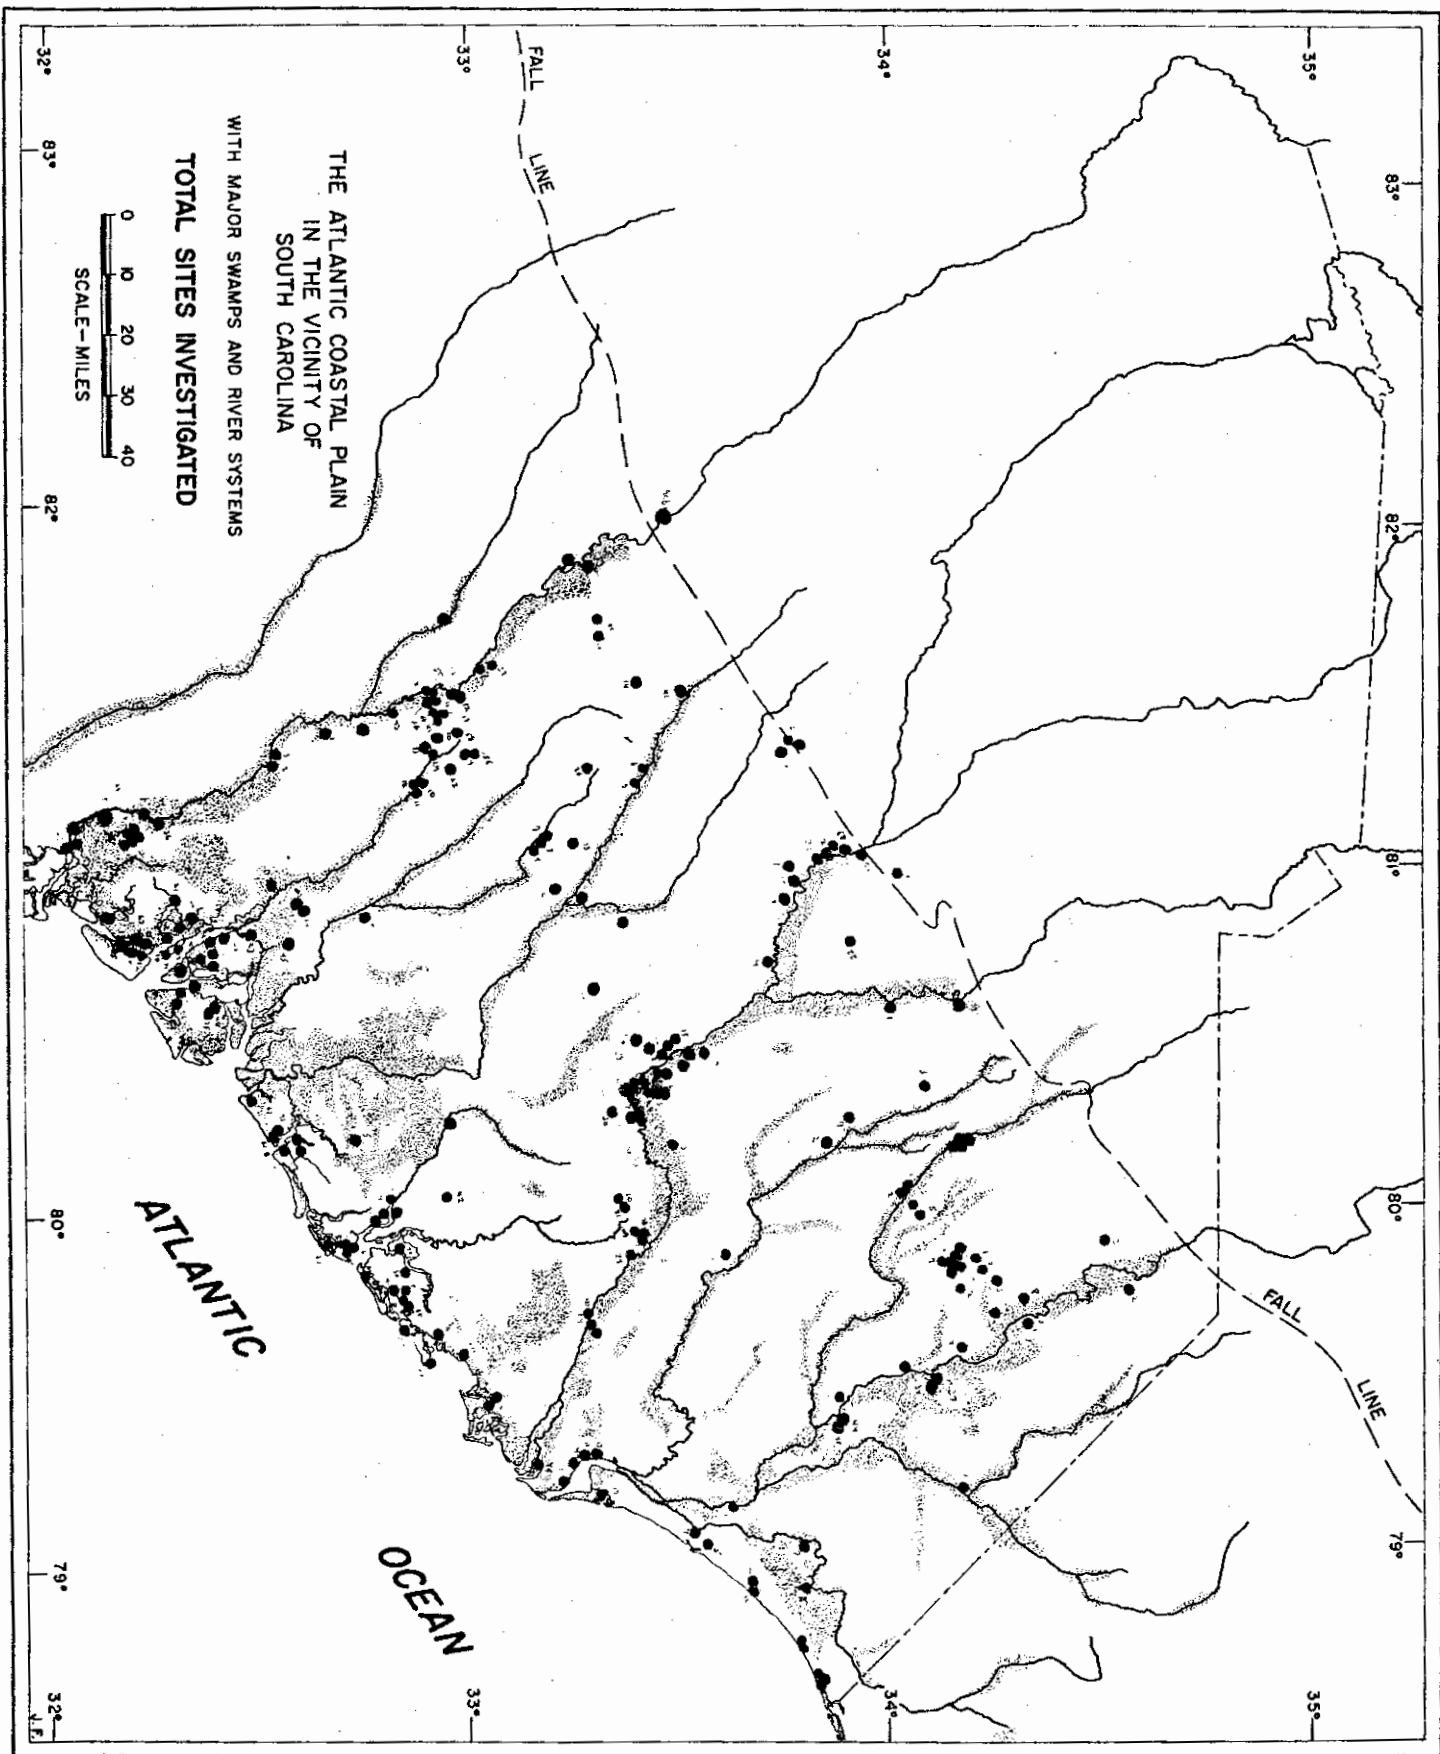

In addition to providing a source of new information the data can be used to check or expand upon earlier work in the region. Waddell's 1965 study and hypothesized distribution of Awendaw finger-pinched ceramics was checked, for an example. Waddell's study indicated that finger-pinched Awendaw ceramics were restricted to the coast with a center of popularity between the Cooper River and Awendaw Creek. The data of this study verifies this; furthermore the decrease in incidence of this ware north and south of this area was found to have a perfect Spearman's r correlation; that is, the further away from Waddell's posited center, the less the ware occurred in a statistically significant pattern.

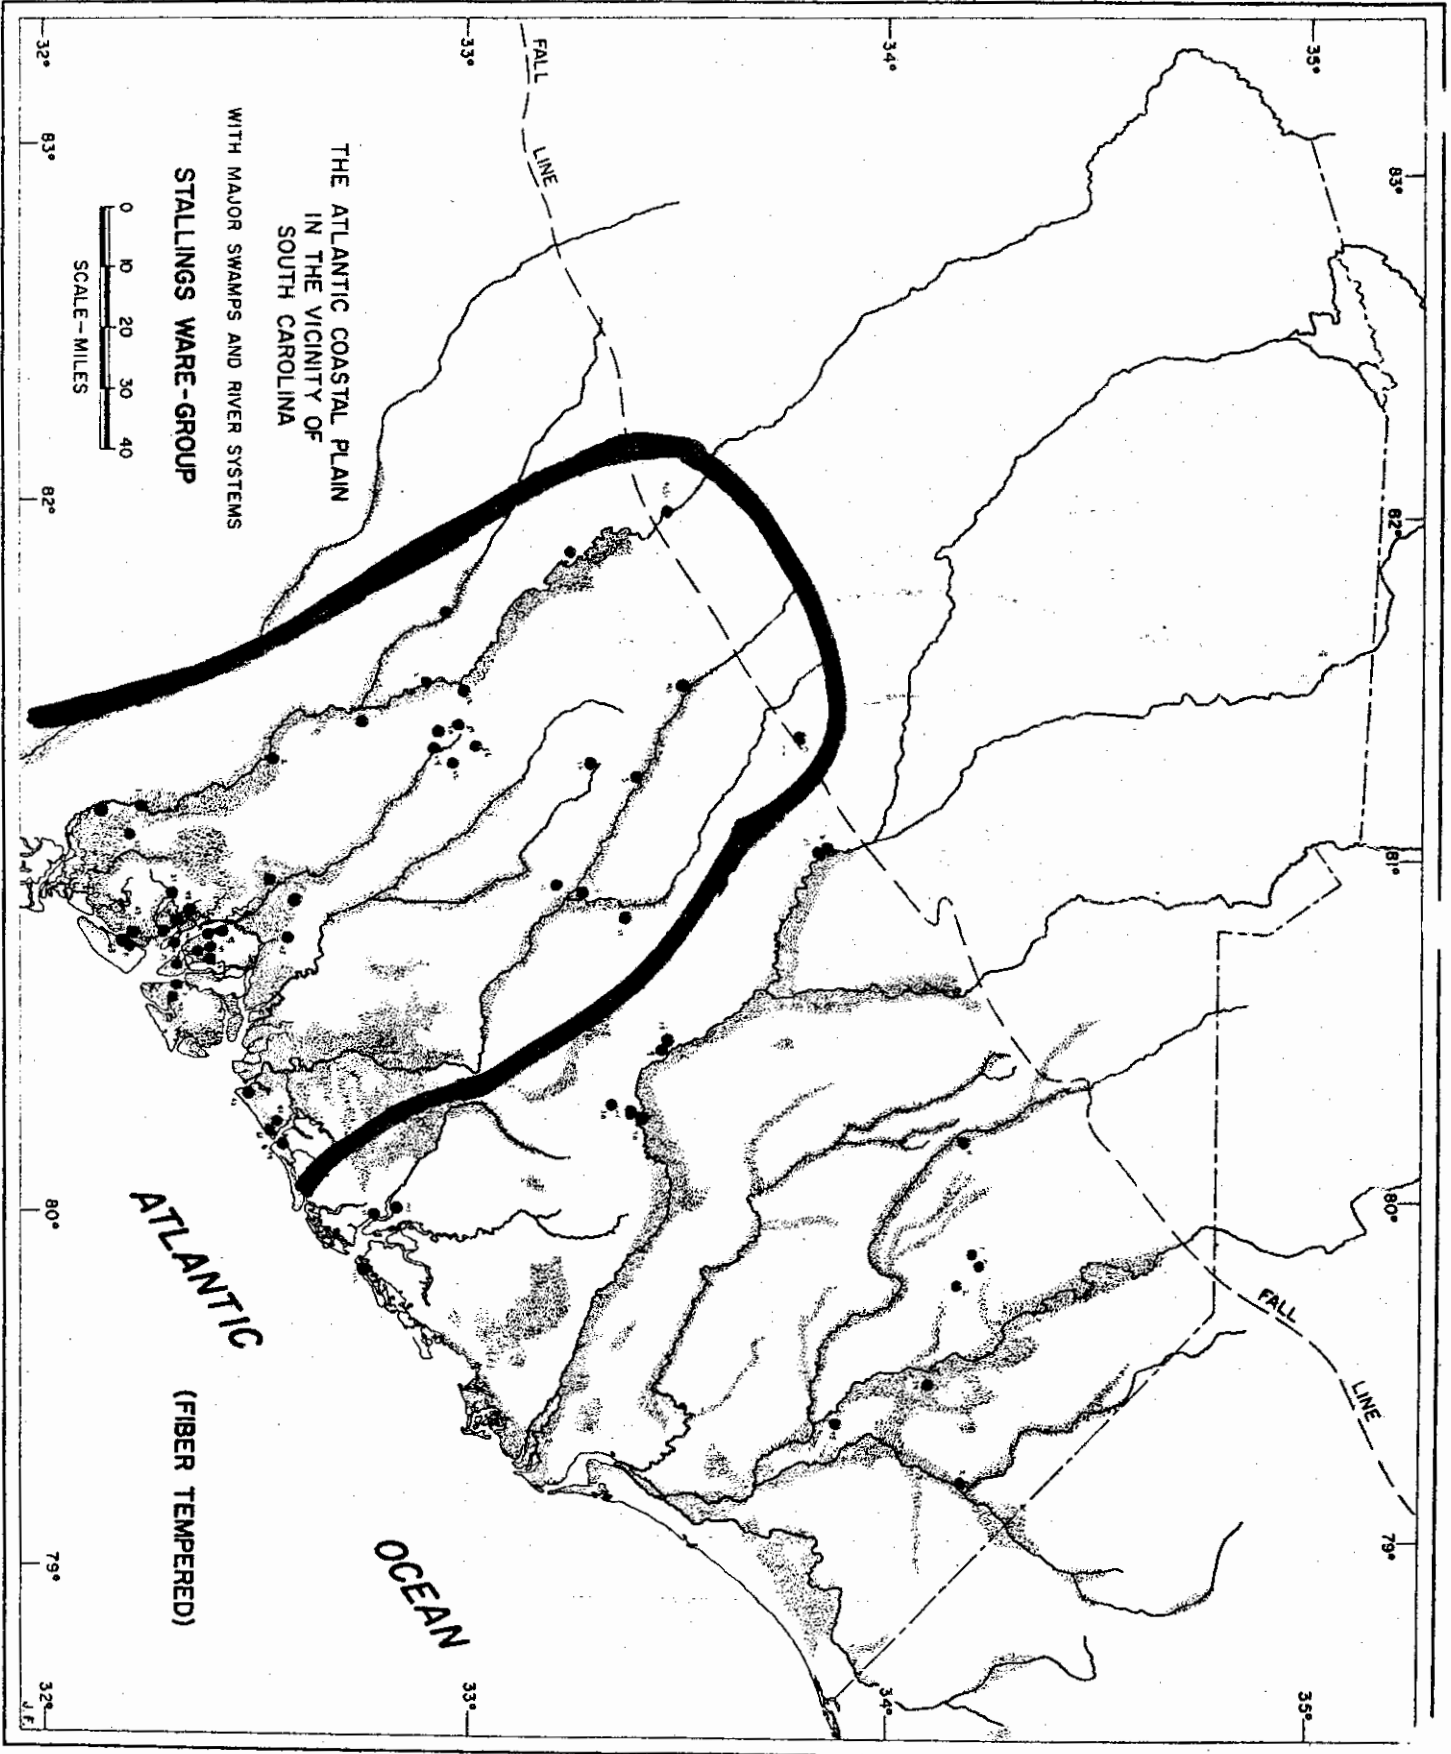

Although this study has yielded some significant information, it has many obvious limitations. It does provide a rough overview of the ceramics found in the coastal plain of South Carolina, and from this hopefully some insight into the way of life of the people who made them. An obvious need for more detailed studies of particular ceramic wares or particular geographic localities exists. Sampling problems encountered here need to be overcome as well; sites reported and collected often tend to cluster where active people such as Waddell, Lee, or Parler live, and the artifacts recovered often indicate a particular collection or research interest rather than what was actually

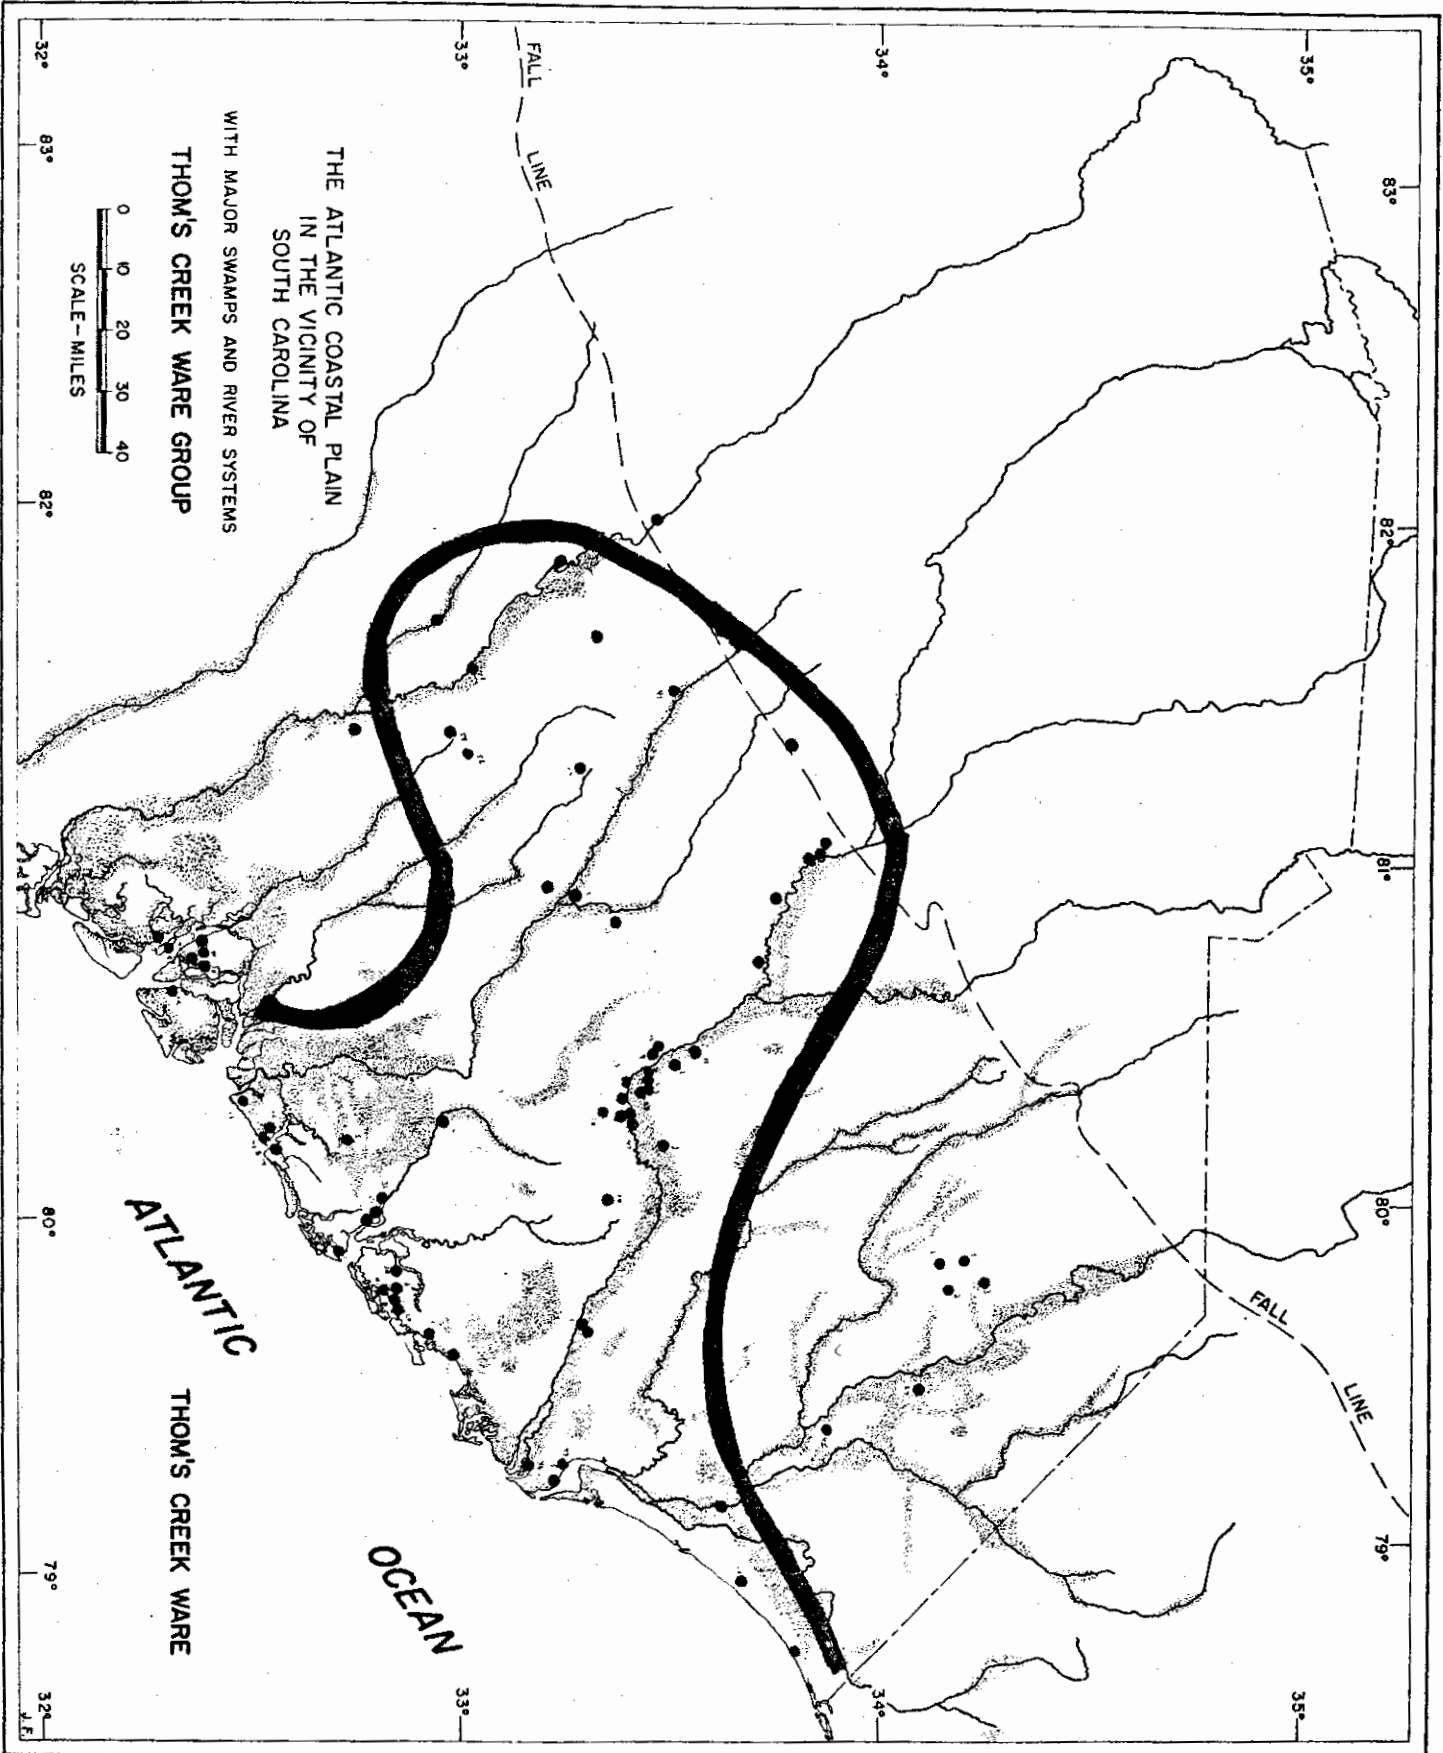

present. Waddell's strong interest in Thom's Creek pottery to a large extent accounts for many of the existing samples from the inland coastal plain of South Carolina.

It is as a data base from which to build more sophisticated models of prehistoric human behavioral patterns on the coastal plain of South Carolina that I feel this study will lend itself in the future. All of the data utilized in the preparation of this report is available for inspection at the Institute of Archeology and Anthropology, the final results of this study will be released under the auspices of the Institute when the research is completed.

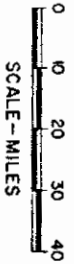

I would especially like at this time to personally thank Stanley South, Albert Goodyear, and Gordon Brown of the IAA staff for their advice and assistance in this project. Joan Combes of the USC computing center, and James Michie, Sammy Lee, Robert Parler, Forest Swails, and Michael Trinkley of the Archeological Society of South Carolina all provided valuable input as well. Finally, in closing I would especially like to thank Leland G. Ferguson of the Institute of Archeology and Anthropology, whose advice, guidance, and active encouragement in a very real sense made this study possible,

Other data Don MacIntosh Collection

Recorded by: David G. Anderson

6 October 1978

Other 38283 subjects

- #142 slate gonyet
- # 143 dark lead
- 144 dent (Allendale) biface (irregular)
- 145 HT Allendale dent ovate biface
- 146, 149 Kinn stemmed \emptyset hafted b. Saccy Allendale dent (A. dent)
- 147 SR stemmed base A. dent
- 148 Expanded hafted biface A. dent (? type)
- 150 Expanded A. dent hafted biface (? type)

(Photo Specimens!)

- 5 sandstone (druid?) fragments
- 3 melted ceramic/glass fragments
- 4 burned stoneware fragments (one damaged)
- 2 bone fragment (hollow) heavily weathered
- 1 pyroclastic fragment 8/64Ms
- 1 plain brass (?) button

U.S.R.M.C.
W 421-0m-2701
9-15-39

- 15 crude quartz shell dent bifaces
- 16 " " " Sec. Dec. Slates
- 15 " " " Interior Slates
- 1 unifaceal orthoquartzite tool (# 1-21)
- 1 rhyolite intarsia plate
- 1 A. dent " " (?)
- 1 green silicate intarsia plate

(HB = hafted biface)

- 1 highly weathered slate # 7p
- 5 orthoquartzite HB. fragment
incl. 1 SR stemmed (# 1-4)
1 Kinn (?) C.N. (# 1-12)
- 1 Allendale dent bifacial
knife (?) (# 1-29)
- 3 quartz shell Kinn stemmed
(# 8, 10, 11)
- 2 Rhyolite HB fragments
- 1 slate SR variant (?)
(# 1-5)
- 1 quartz mm 2 (# 1-6)
- 1 quartz mm 1 (?) (# 1-9)
- 1 quartz mm 1 (?) (# 1-1)

Other data 2 local clay
objects (pottery fragments?)
and several fragments of
limonitic sandstone also
present.

Recorded by:
 David B. Anderson

Date:
 2 October 1978

Several hundred shards, mainly plain or Daytonian shell stamped

2-9 highly fossilized (ogelized shell) Dayton points;

2-19 fragment, broken

2-10 quartzite Dayton or below like
(many shards exhibit mounding holes)

2-11, } Late Archaic ^{Na} ~~Delaware~~ like pl/sk variants quartz, quartzite
2-17 }

2-6 } Woodland (early) like etc(?)
2-2 }

2-28 Kankakee (mass?)

2-5 (vaguely like coned Yolli?)
bed?

Considerable fired clay (probable dark, some brownish, so w/ shell impressions)
(structure!); lots 18th - early 19th century pottery (pearlware), nails (cut and wire);
some cord and fabric (Edge Farm) materials.

2-132 congl stone shell (? type). 2 specimens,
also 2-392 " " "

2-227 - Refuge late to stamped shell.

County: Clarendon State: _____ Site No: _____
Site Name: _____ Feature No: _____
Continuation sheet for: _____

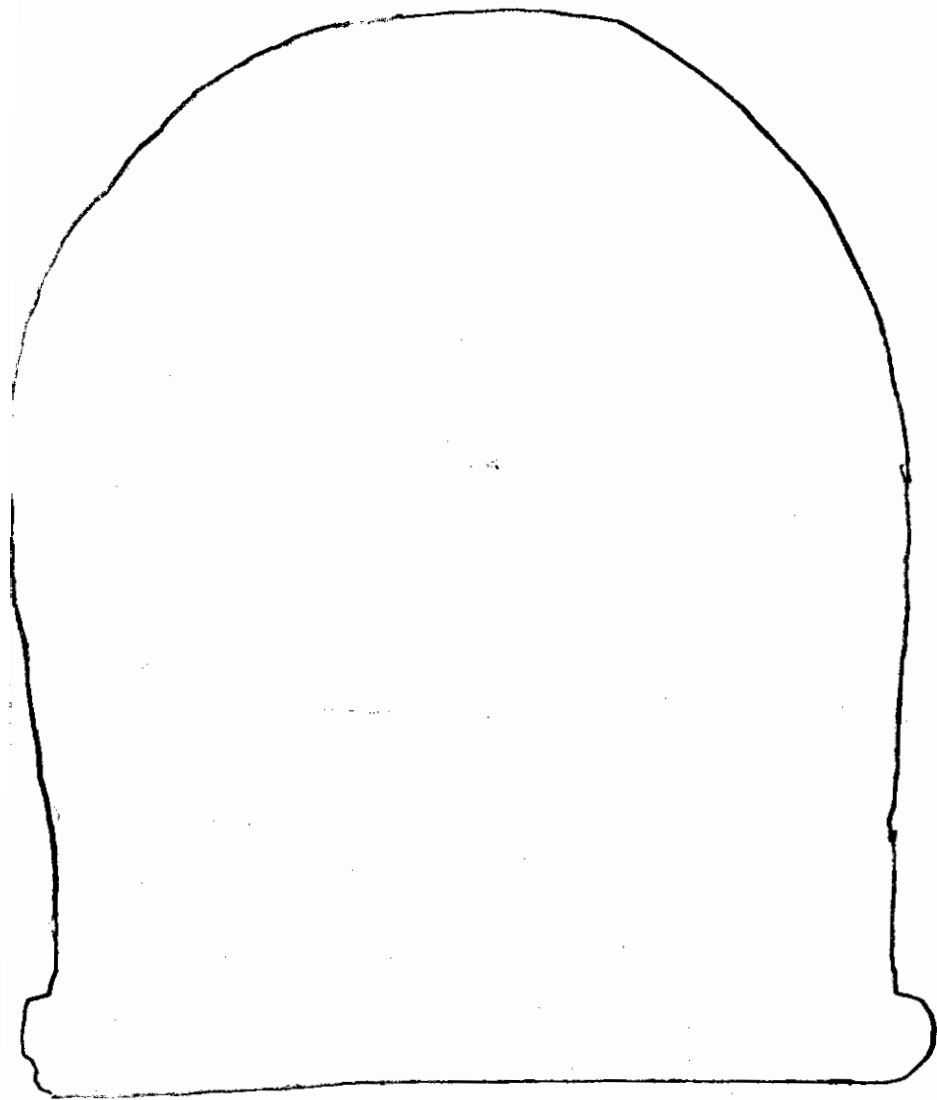

Item No. 64.64.3 Data
Indian urn, washed out (of Lake Marion) by wave
action. 5" high. Slightly flattened bottom. Gift of
Glen David Stone, Rte 4, Box 251, Manning, S.C. 10/24/67
Pee Dee series, two separate stamps appear to have
been applied. Base - 1/2 way to rim has cross ; remainder
of vessel to rim a variation of the bar cross with partial
fillet.  -  Rim - notched applique strip,
slightly flaring.  interior burnished plain
Color 5YR 2.5/15 black to dull reddish brown over 90%,
some mottling (see on interior) to ^{2.5YR/5/6} red
4 1/2" outside in diameter (9.0 in) Clay/grit paste

64.64.1 - Found same as above, same person. ^{exterior} Urn 6 3/4" high
Pee Dee series, bar cross fillet over all surface. (Same
series as upper part of vessel 64.64.3. Base rounded
leading slightly to cordal. Rim slightly flaring with
two rows of real punctations (1/4 and 5/8" ^{approx} approximately)
below rim. (9.0 in). Five sets of two insets (3/4"
apart ^{center to center}) each one equally spaced down
rim of the vessel, ^{near rim} 3/8" ⁱⁿ inch below the rim. One ^{row} broken
off, space where it should be. Interior smoothed. Paste
fine sand/clay with grit. Mottled (fine clouded exterior from
50% interior (lower section near base) dull. Mottling
colors dull - 5YR 4/1.5 dull gray - dull reddish gray.
Remains 5YR 5.5/6 yellowish red - reddish yellow

Recorded by Paul S. Anderson Date: 16 Sept 1974

CONTINUATION SHEET

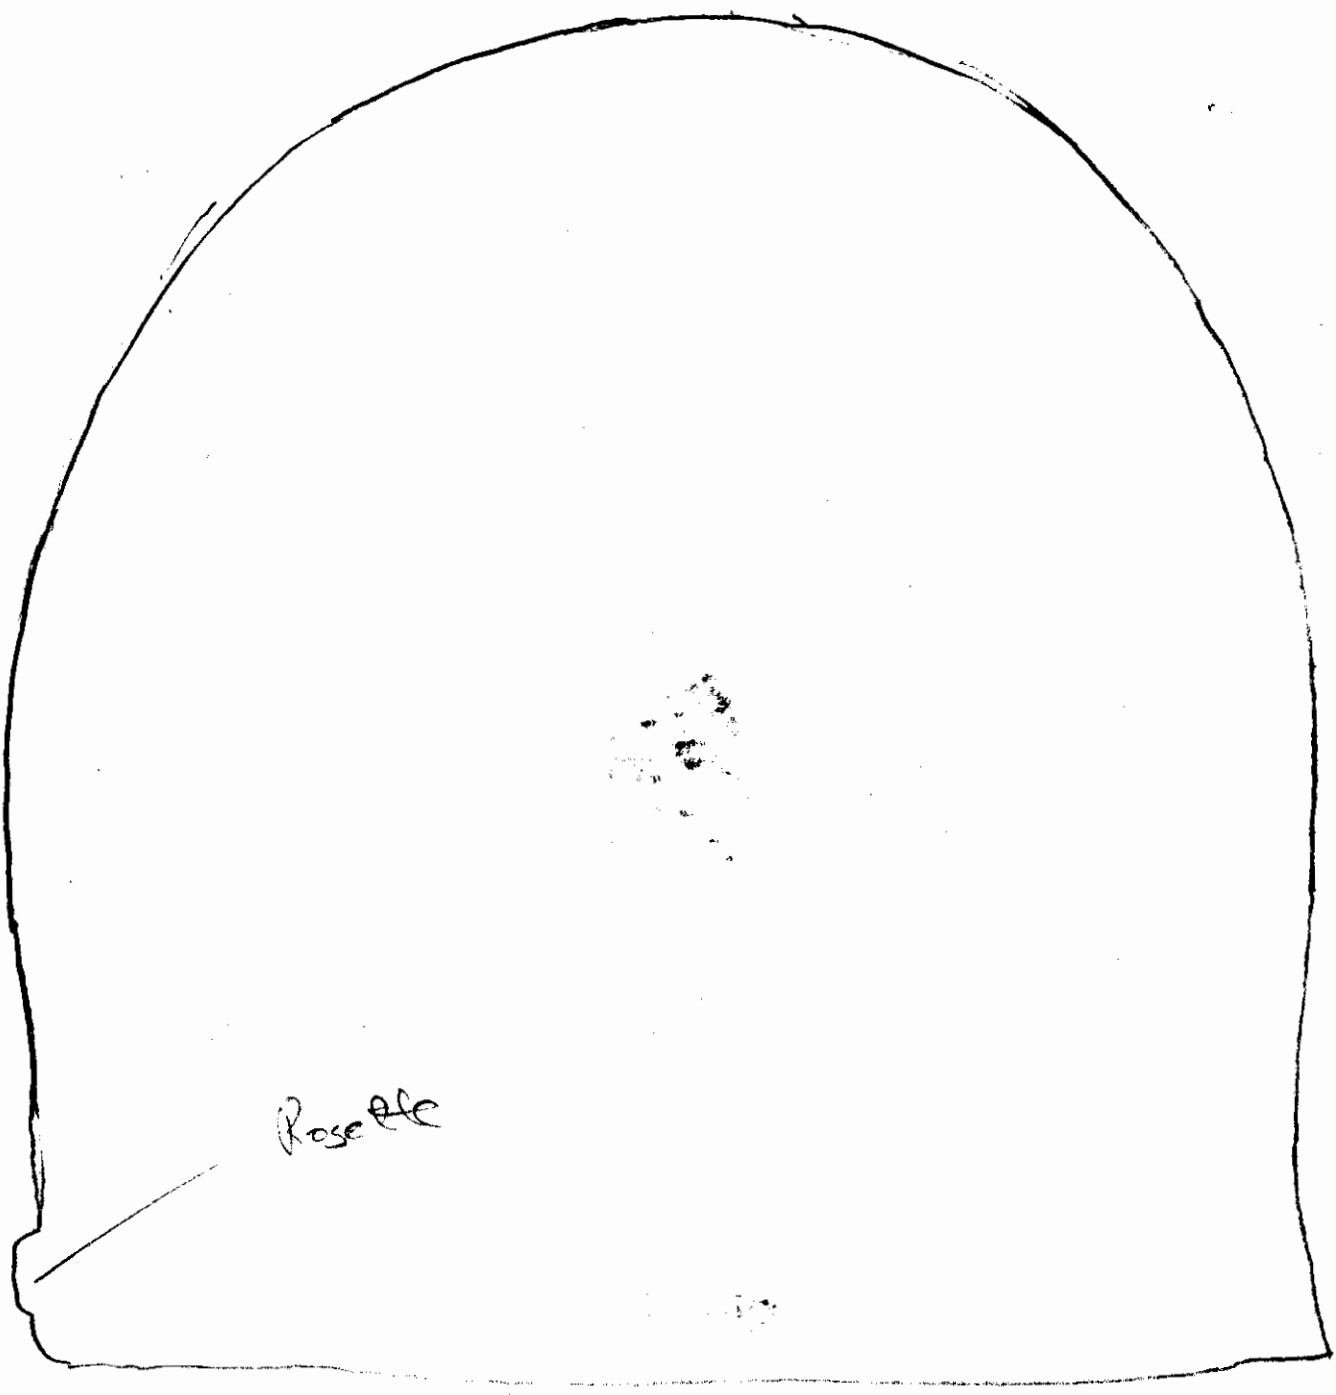

County: Clarendon State: _____ Site No: _____
Site Name: _____ Feature No: _____
Continuation sheet for: _____

Item No. Data

64.64.2 Same as 64.64.1 and 3 for discovery

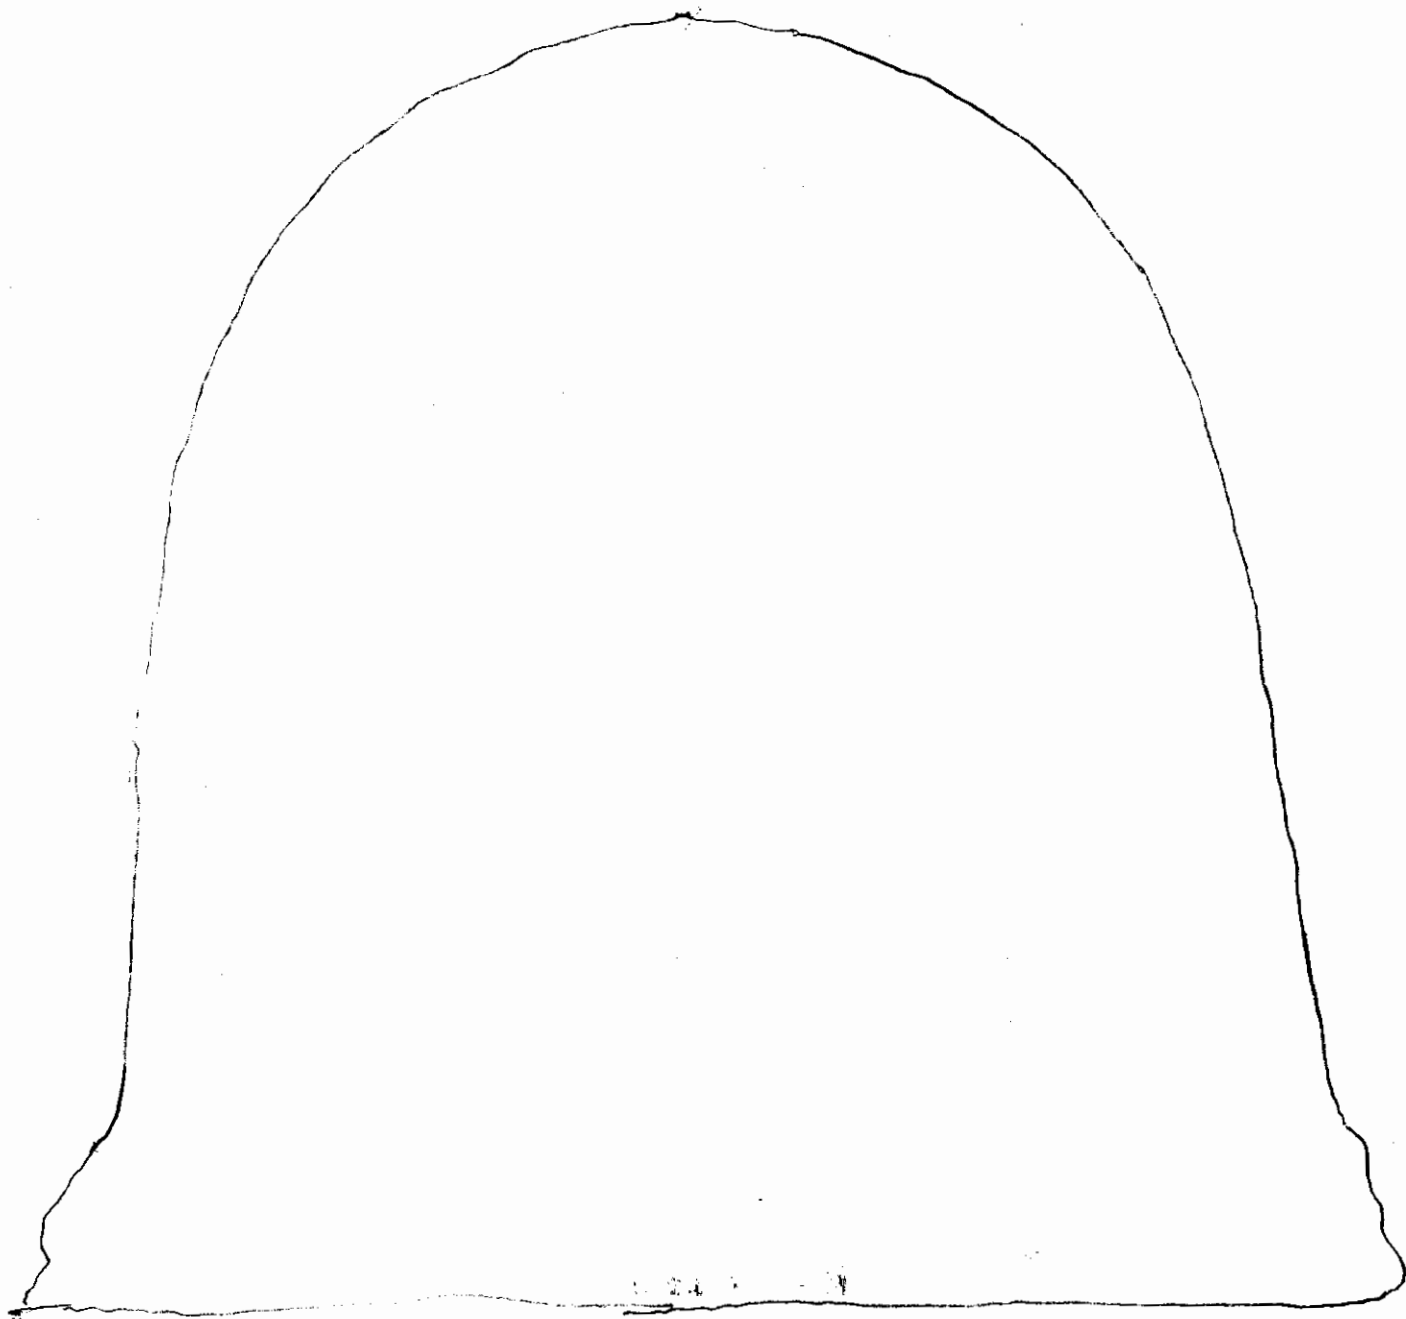

Pee Dee series small urn, stamped with bar-cross and four-cross with fillet (see also two vessel descriptions)
Stamping faint or worn away on base; vessel apparently was smoothed somewhat here. The base also shows fiber marks ~~from~~ probably caused by the vessel resting on a bed of grass or large sticks in the plastic state. Rounded base, flaring rim. A row of vesicles is located 1/2 inch below the rim, and a row of punctures (round, circular) is located below it (roughly below each vesicle) 3/4"-1" below the rim. Vessel heavily over-stamped in areas. Exterior smoothed. Paste fine sand-dry/grit. Exterior mostly fine doped with slight lighter mottling, possibly due to wear. Interior largely light oxidized except for some clouding near base. Colors - clouding 5YR 4.5/1 ~~reddish~~ dark gray-gray, interior 2.5YR 5/6 - red
Rim shows finger pressing along surface (13P)

Recorded by David S. Anderson Date: 16 September 1974
